G12230-512WB

**Employs two InGaAs chips (cutoff wavelength: 1.65  $\mu\text{m}$ , 2.15  $\mu\text{m}$ )  
Near infrared image sensor (0.95 to 2.15  $\mu\text{m}$ )**

The G12230-512WB is an InGaAs linear image sensor designed for near infrared multichannel spectrophotometry. Two InGaAs chips with different cutoff wavelengths are arranged very accurately in series. The G12230-512WB provides high S/N over a wide spectral response range. The CMOS chip consists of charge amplifiers, a shift register, and a timing generator. Charge amplifiers are configured with CMOS transistor array and are connected to each pixel of the InGaAs photodiode array. Since the signal from each pixel is read in charge integration mode, high sensitivity and stable operation are attained in a wide spectral response range. The package is hermetically sealed providing excellent reliability.

The signal processing circuit on the CMOS chip enables the selection of an optimum conversion efficiency (CE) for your application from the available two types using external voltage.

## Features

- Employs two InGaAs chips
- Selectable from two conversion efficiency types
- Built-in saturation countermeasure circuit
- Built-in CDS circuit\*<sup>1</sup>
- Built-in thermistor
- Easy operation (built-in timing generator\*<sup>2</sup>)
- High resolution: 25  $\mu\text{m}$  pitch

## Applications

- Near infrared multichannel spectrophotometry
- Non-destructive inspection equipment

\*1: A major source of noise in charge amplifiers is the reset noise generated when the integration capacitance is reset. However, the CDS circuit, which takes the difference between the signal after the completion of the integration time and the signal immediately after resetting, greatly reduces the reset noise.

\*2: Different signal timings must be properly set in order to operate a shift register. In conventional image sensor operation, external PLDs (programmable logic device) are used to input the required timing signals. However, the image sensors internally generate all timing signals on the CMOS chip just by supplying CLK and RESET pulses. This makes it simple to set the timings.

### Electrostatic countermeasures

This device has a built-in protection circuit against static electrical charges. However, to prevent destroying the device with electrostatic charges, take countermeasures such as grounding yourself, the workbench and tools to prevent static discharges. Also protect this device from surge voltages which might be caused by peripheral equipment.
